# Electroporation - < 48 Hour reporter assay

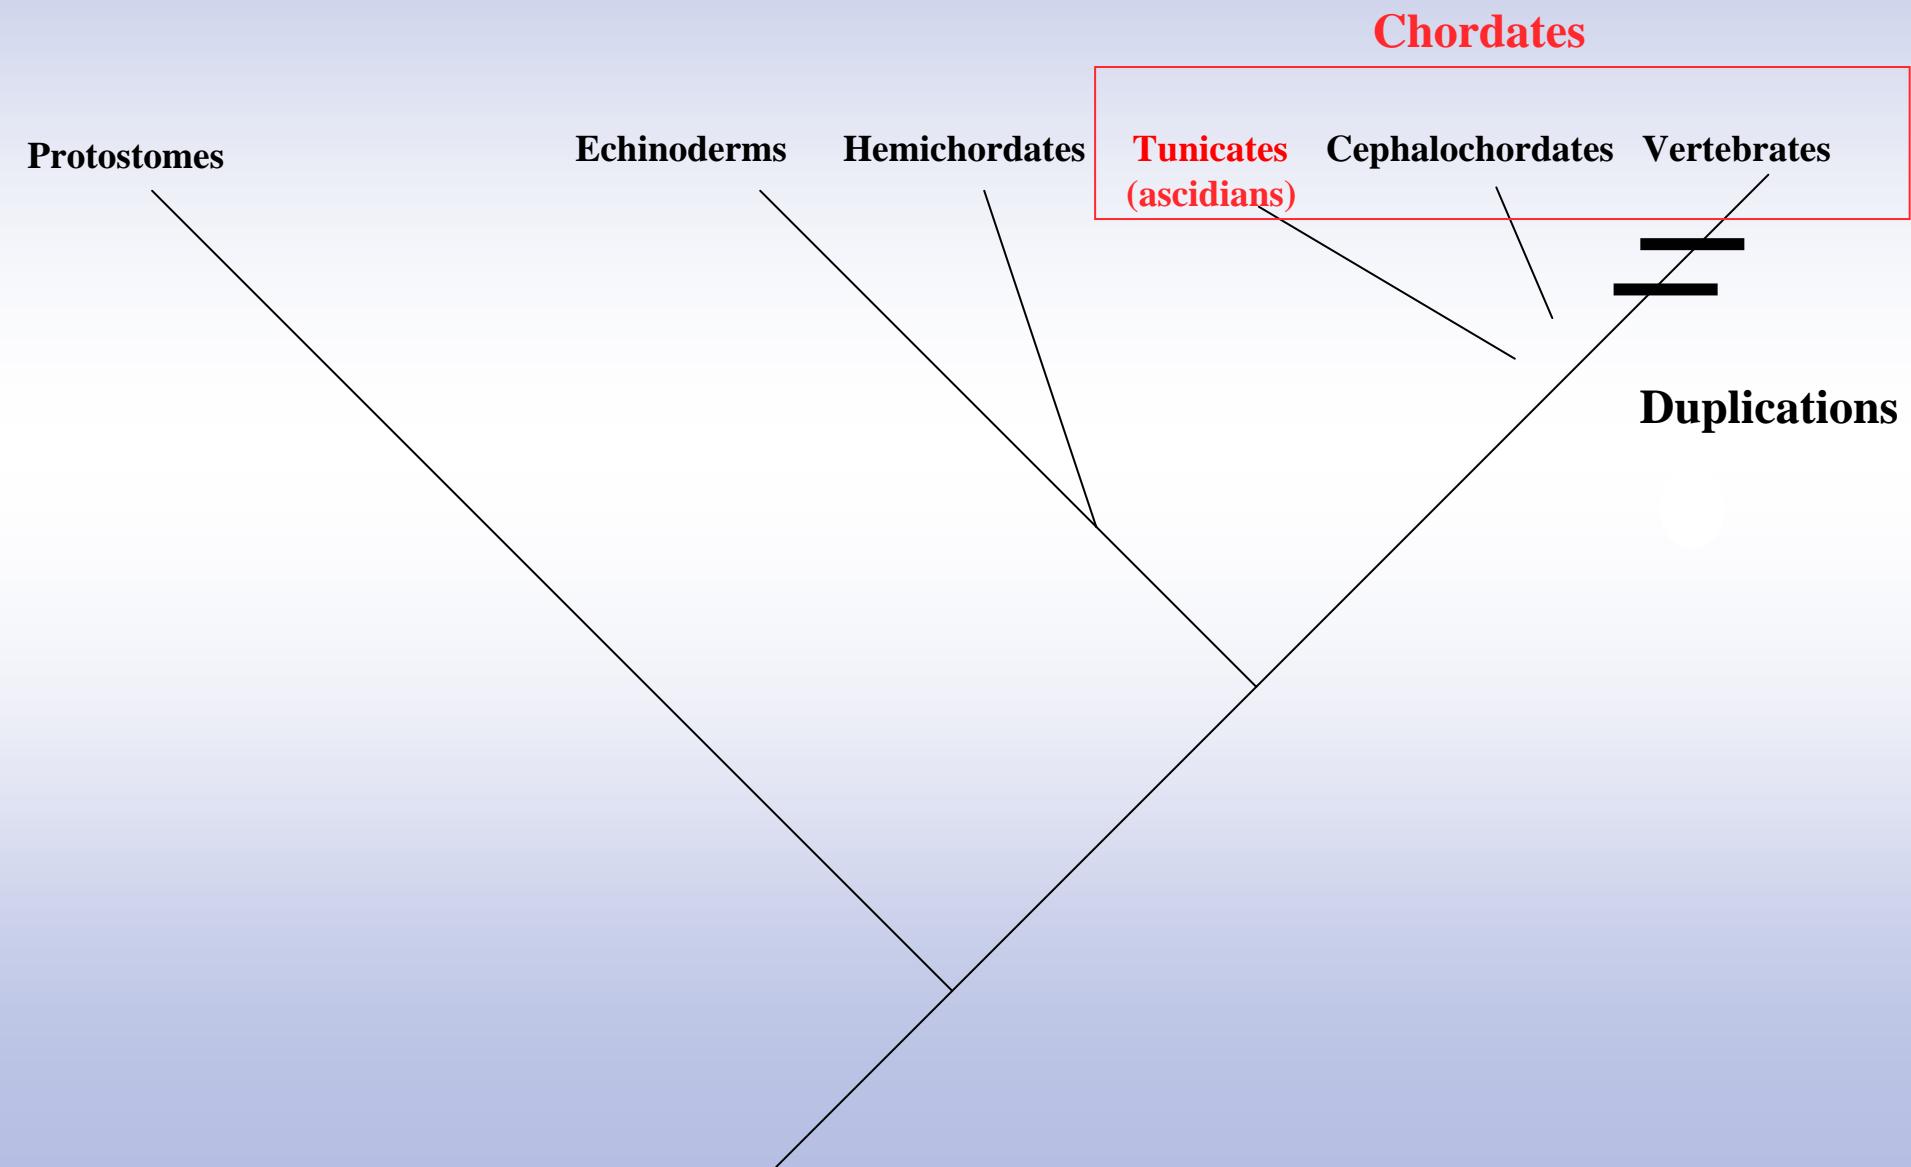

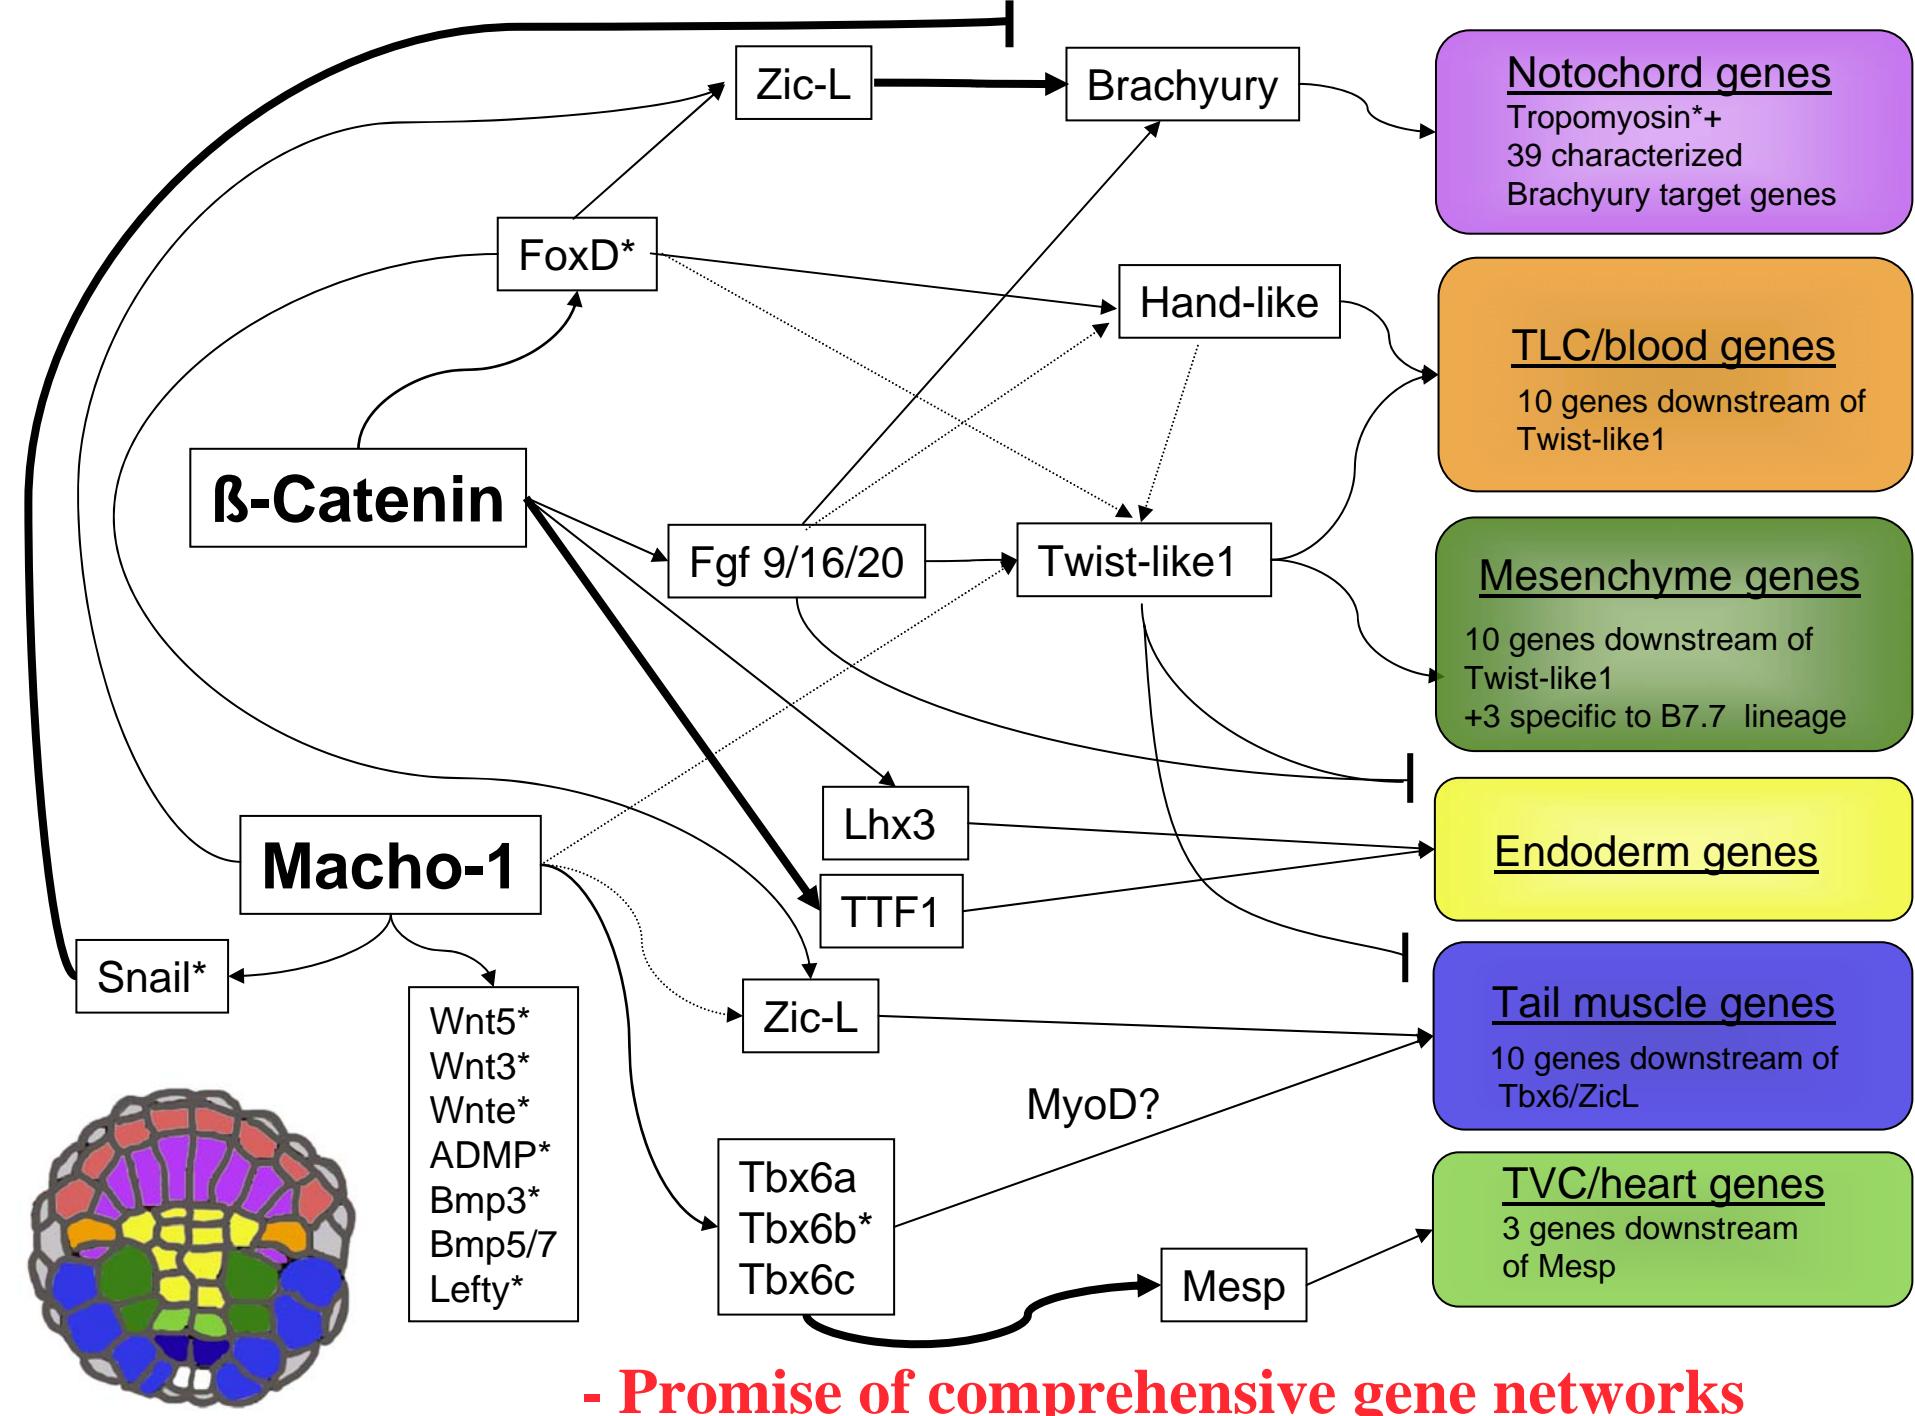

## Stable Transgenics

Time to maturation : 3 months; Life span 1-2years

# Single orthologs/morpholino injections

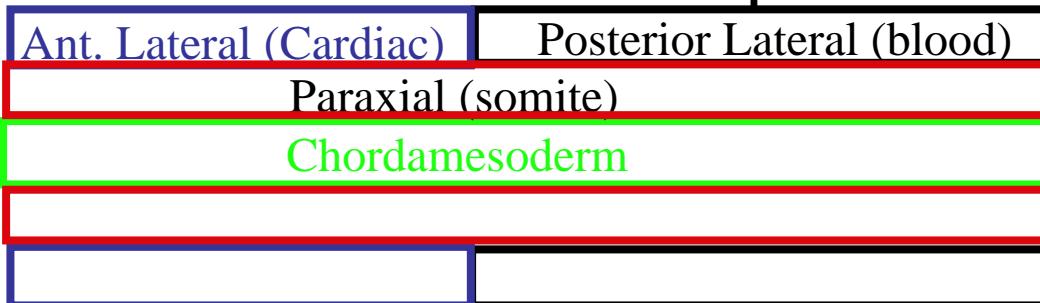

# Outline

1. Introduction to the Tunicates
2. Why study *Ciona*?
3. Why study *Ciona* heart development?
4. Mesp regulation
5. Mesp function
6. Evolutionary implications

# Current Model for Vertebrate Heart Specification Fly

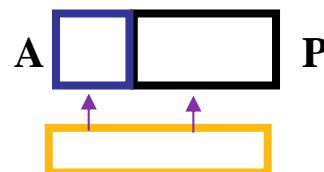

1. Prior to gastrulation mesodermal cell fates are unspecified.

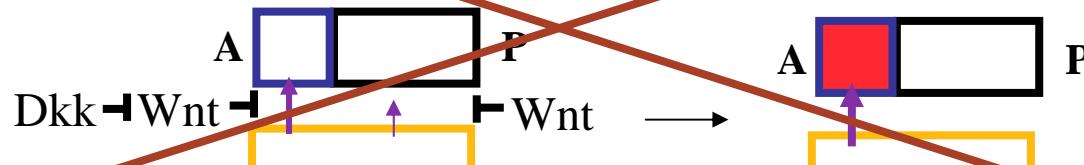

Dpp

Ectoderm maintains

2. During gastrulation **Bmp (+ ?)** secreted by **endoderm** initiates cardiac specification.

3. Induction is prevented in posterior by Wnt signals  
(blocked by DKK in anterior)

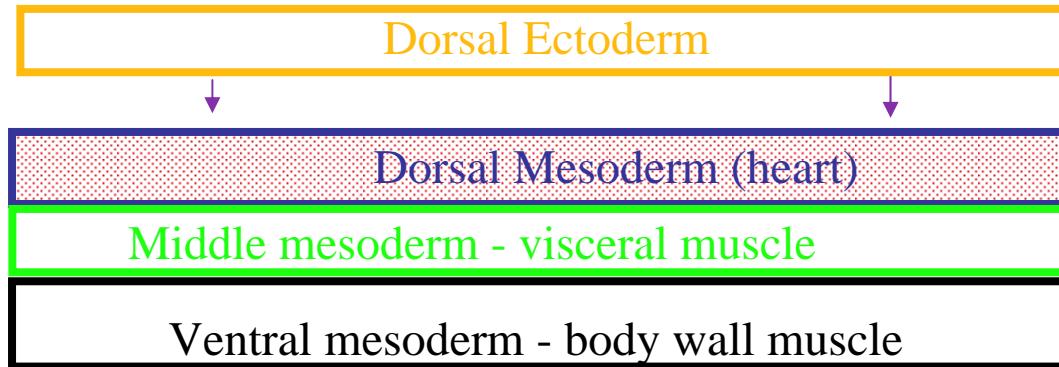

Heart genes:  
**Nkx2.5, Gata, etc.**  
**Tinman, Pannier**

# Current Model for Fly Heart Specification

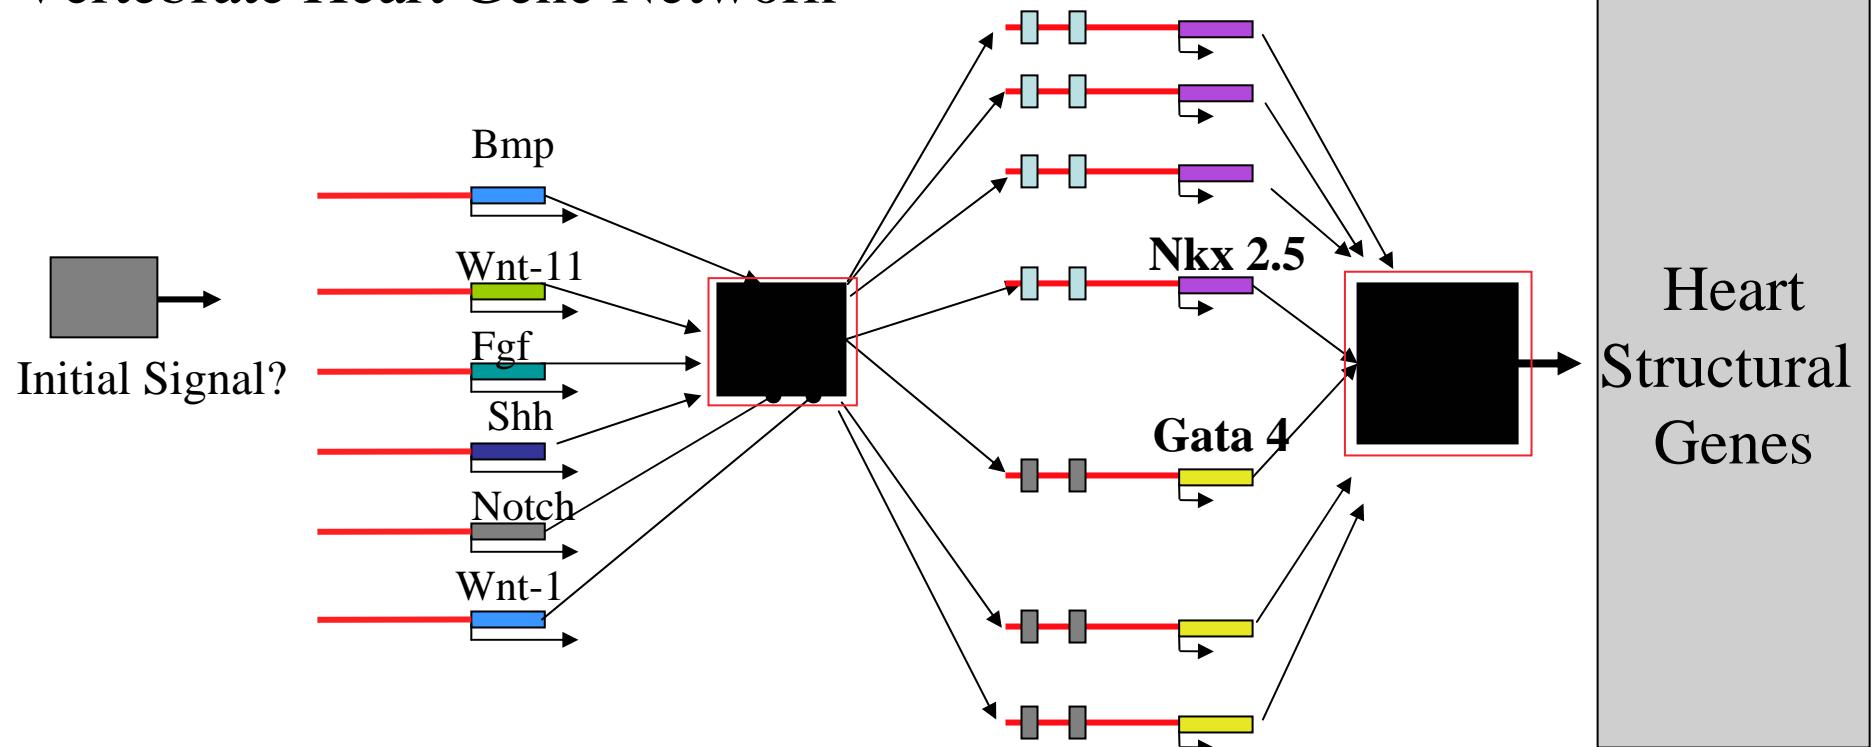

1. Prior to gastrulation the heart factor **Tinman** (**Nkx2.5**) is expressed in all mesoderm.

2. During gastrulation **Dpp** (+ ?) secreted by dorsal ectoderm maintains **Tinman**, activates **Pannier**.

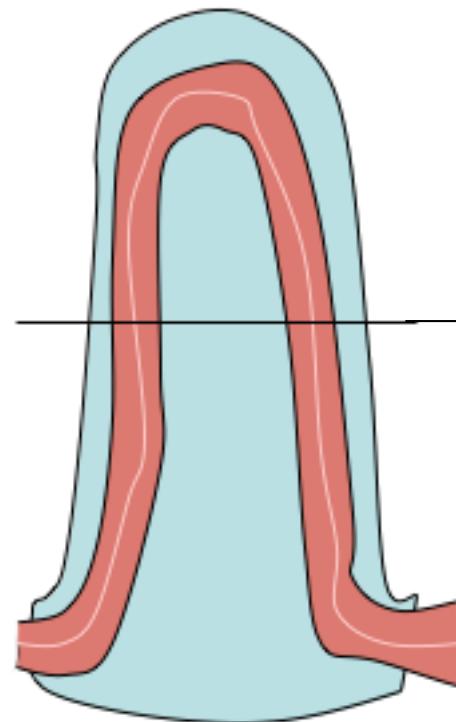

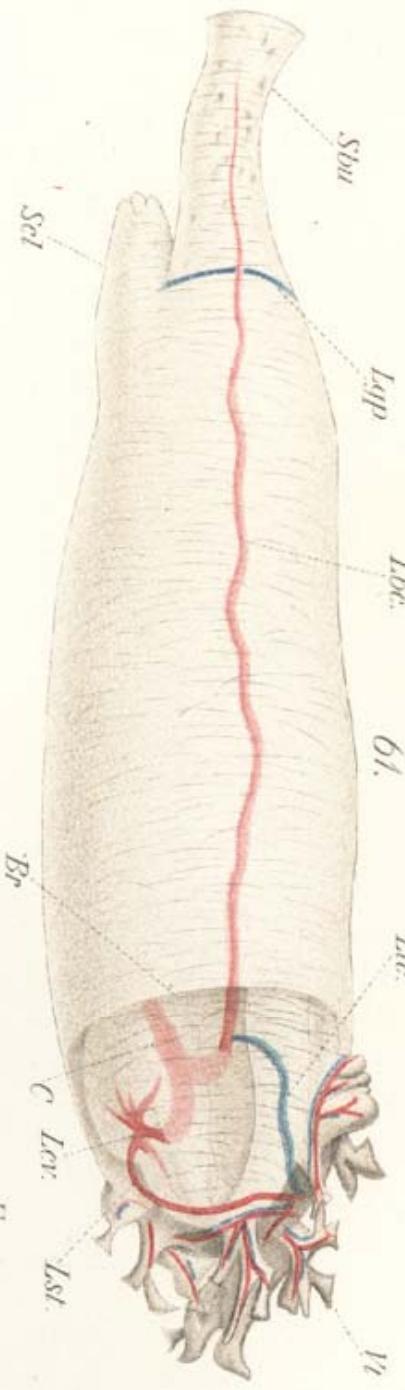

# Vertebrate Heart Gene Network

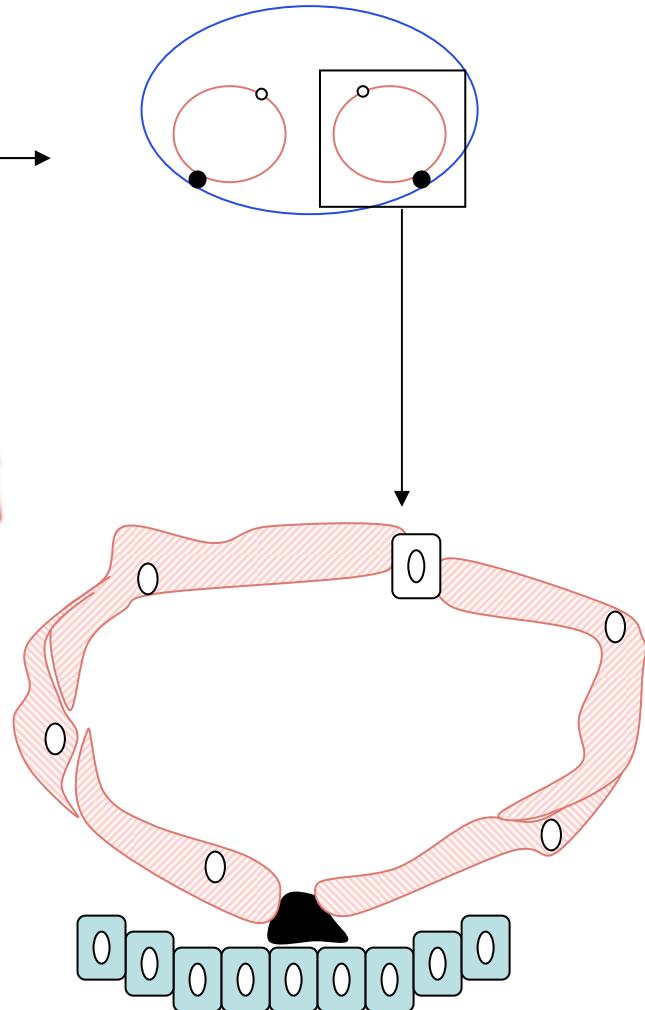

## Conundrums...

1. Initial signals?
2. Key transcription factors are redundant.
3. What are the interconnections? (Black Boxes)

# Ciona heart morphology

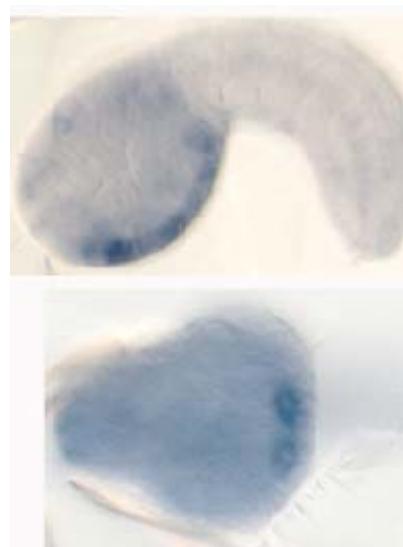

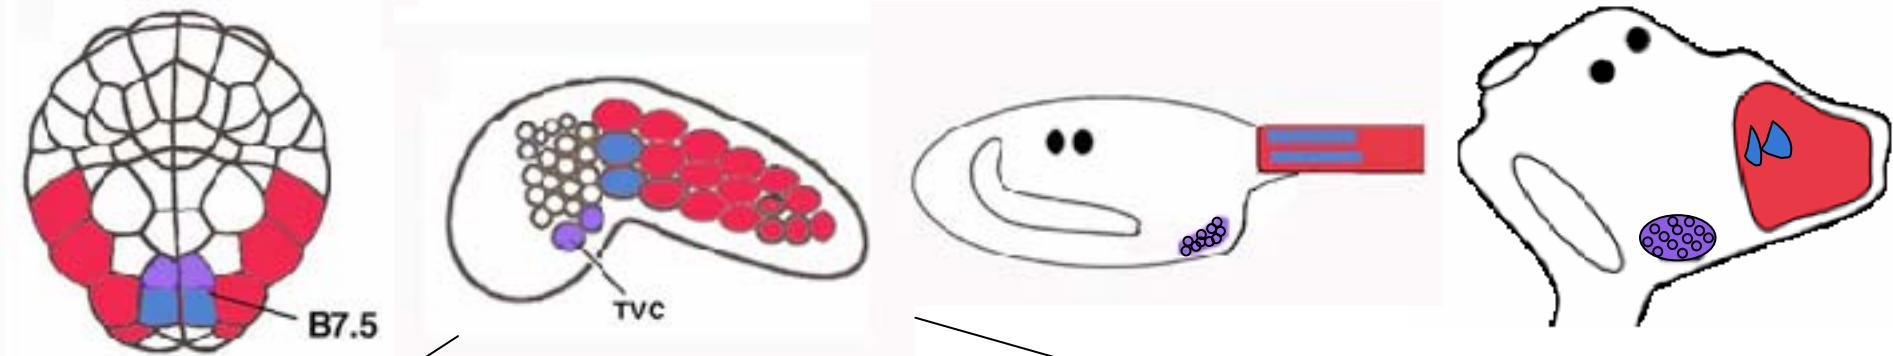

**Pericardium / Myocardium**

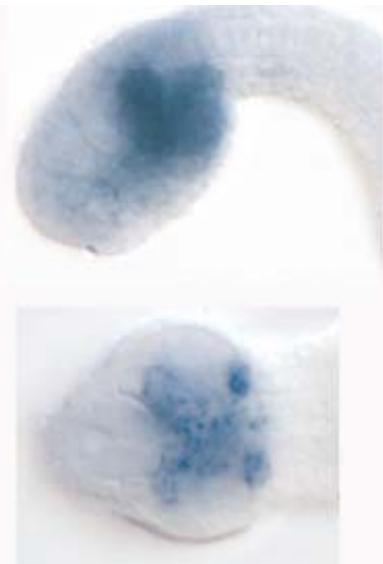

# Heart movie

Dorsal vessel

Protostomes

## 1. Chordate specific heart genes?

Why recruited?

## 2. Chamber evolution.

Ancestral 1 or 2?

Conserved Genes?

**Chordates**

Multiple chambers  
(atria/ventricles)

Ventral/Anterior  
Heart

Conserved “initial” heart  
specification (Bmp/Nkx/Gata)

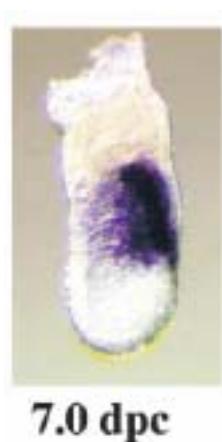

# Outline

1. Introduction to the Tunicates
2. Why study *Ciona*?
3. Why study *Ciona* heart development?
4. Mesp regulation
5. Mesp function
6. Evolutionary implications

# Mesp (bHLH) and Heart Cell Migration:

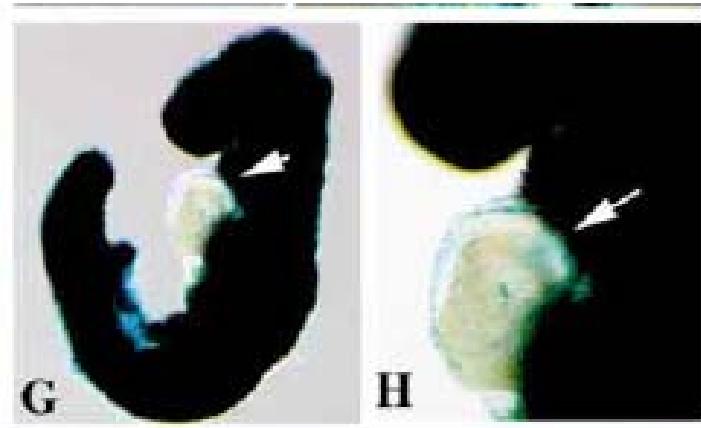

Mouse: (Kitajima, Saga, 1999, 2000)

- Mesp1 expression

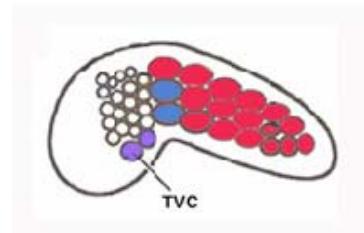

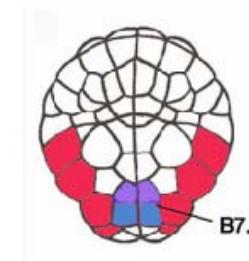

7.0 dpc

Function: blue cells = Mesp1/2 KO

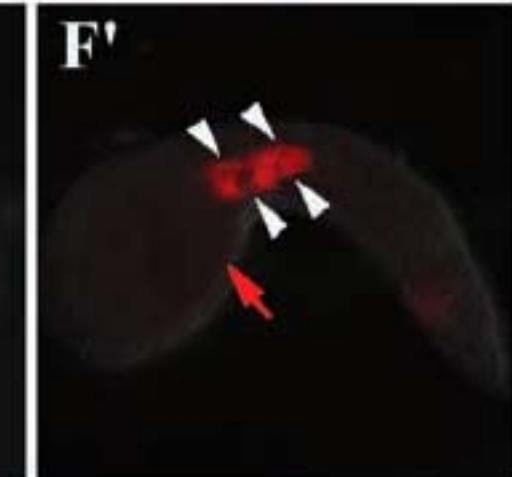

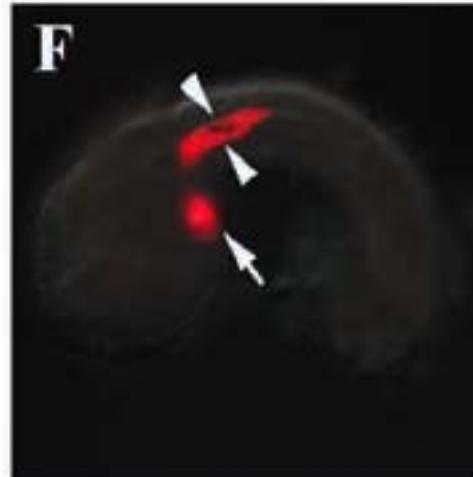

## Ascidian

Mesp Expression:

Function: Normal

Mesp-KO (Satou et al., 04)

# Two Questions about Mesp

- What activates Mesp?
- Is Mesp involved in Migration or Specification?

# Outline

1. Introduction to the Tunicates
2. Why study *Ciona*?
3. Why study *Ciona* heart development?
4. Mesp regulation
5. Mesp function
6. Evolutionary implications

# Manipulation of Mesp function

## 1. Isolate DNA Binding Domain

## 2. Attach 3' domain

Repression

Activation

■■-Vp16

## 3. Express in heart lineage

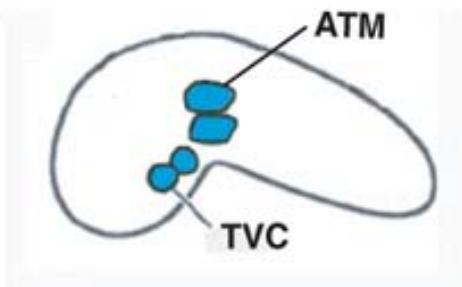

Mesp Enhancer

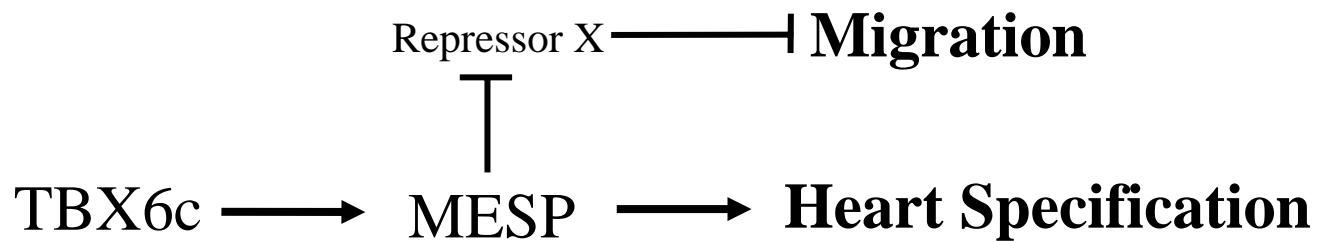

Mesp Enhancer

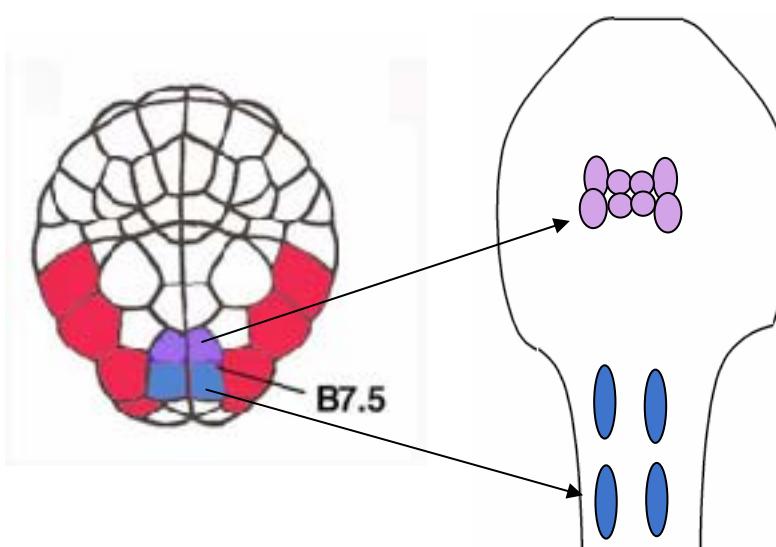

a

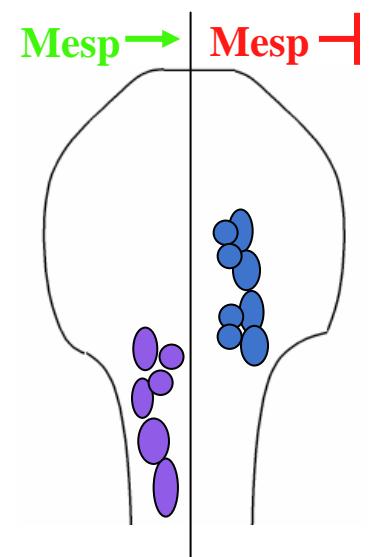

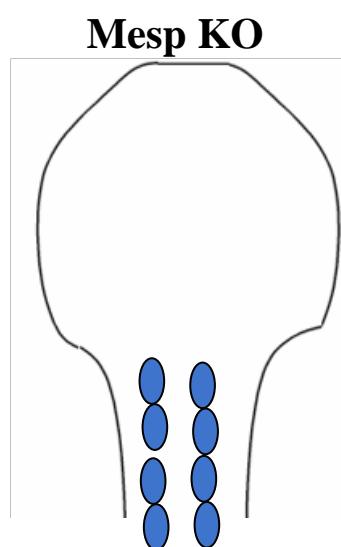

**TVCs (*Hndx*)  
migrate and  
divide**

**Anterior Tail  
Muscle  
(*Raldh2*)**

# Outline

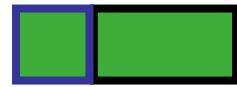

1. Introduction to the Tunicates
2. Why study Ciona?
3. Why study Ciona heart development?
4. Mesp regulation
5. Mesp function
6. Evolutionary implications
  - a. Early vertebrate heart specification
  - b. Recruitment of Mesp in chordate heart dev.
  - c. Mesp and the Germ Plasm
  - d. Chamber evolution

## Vertebrate

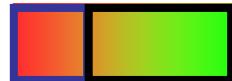

Cardiac/paraxial (somite)

Tbx6

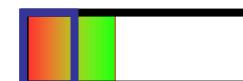

Mesp on

## Ciona

Cardiac/Tail muscle

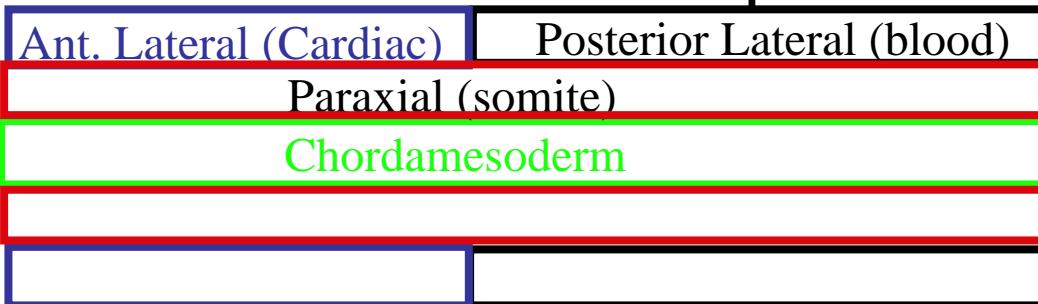

**In Vertebrates:**

**Mesp initially induces a broad potential cardiac field**

# Current Model for Vertebrate Heart Specification

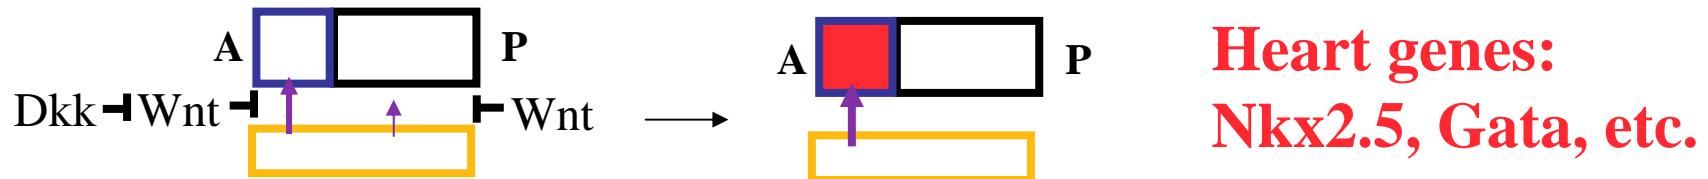

1. Prior to gastrulation mesodermal cell fates are unspecified.

2. During gastrulation Bmp (+ ?) secreted by endoderm initiates cardiac specification.

3. Induction is prevented in posterior by Wnt signals  
(blocked by DKK in anterior)

# New Model for Vertebrate Heart Specification

New Vertebrate Model: Endoderm signal for maintenance, not inducer.

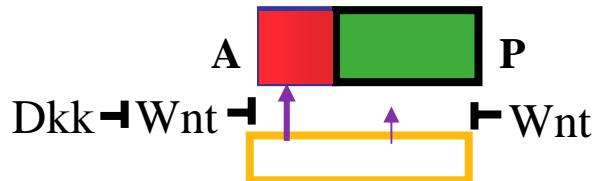

## 1. Tbx -> Mesp creates initial broad potential heart field.

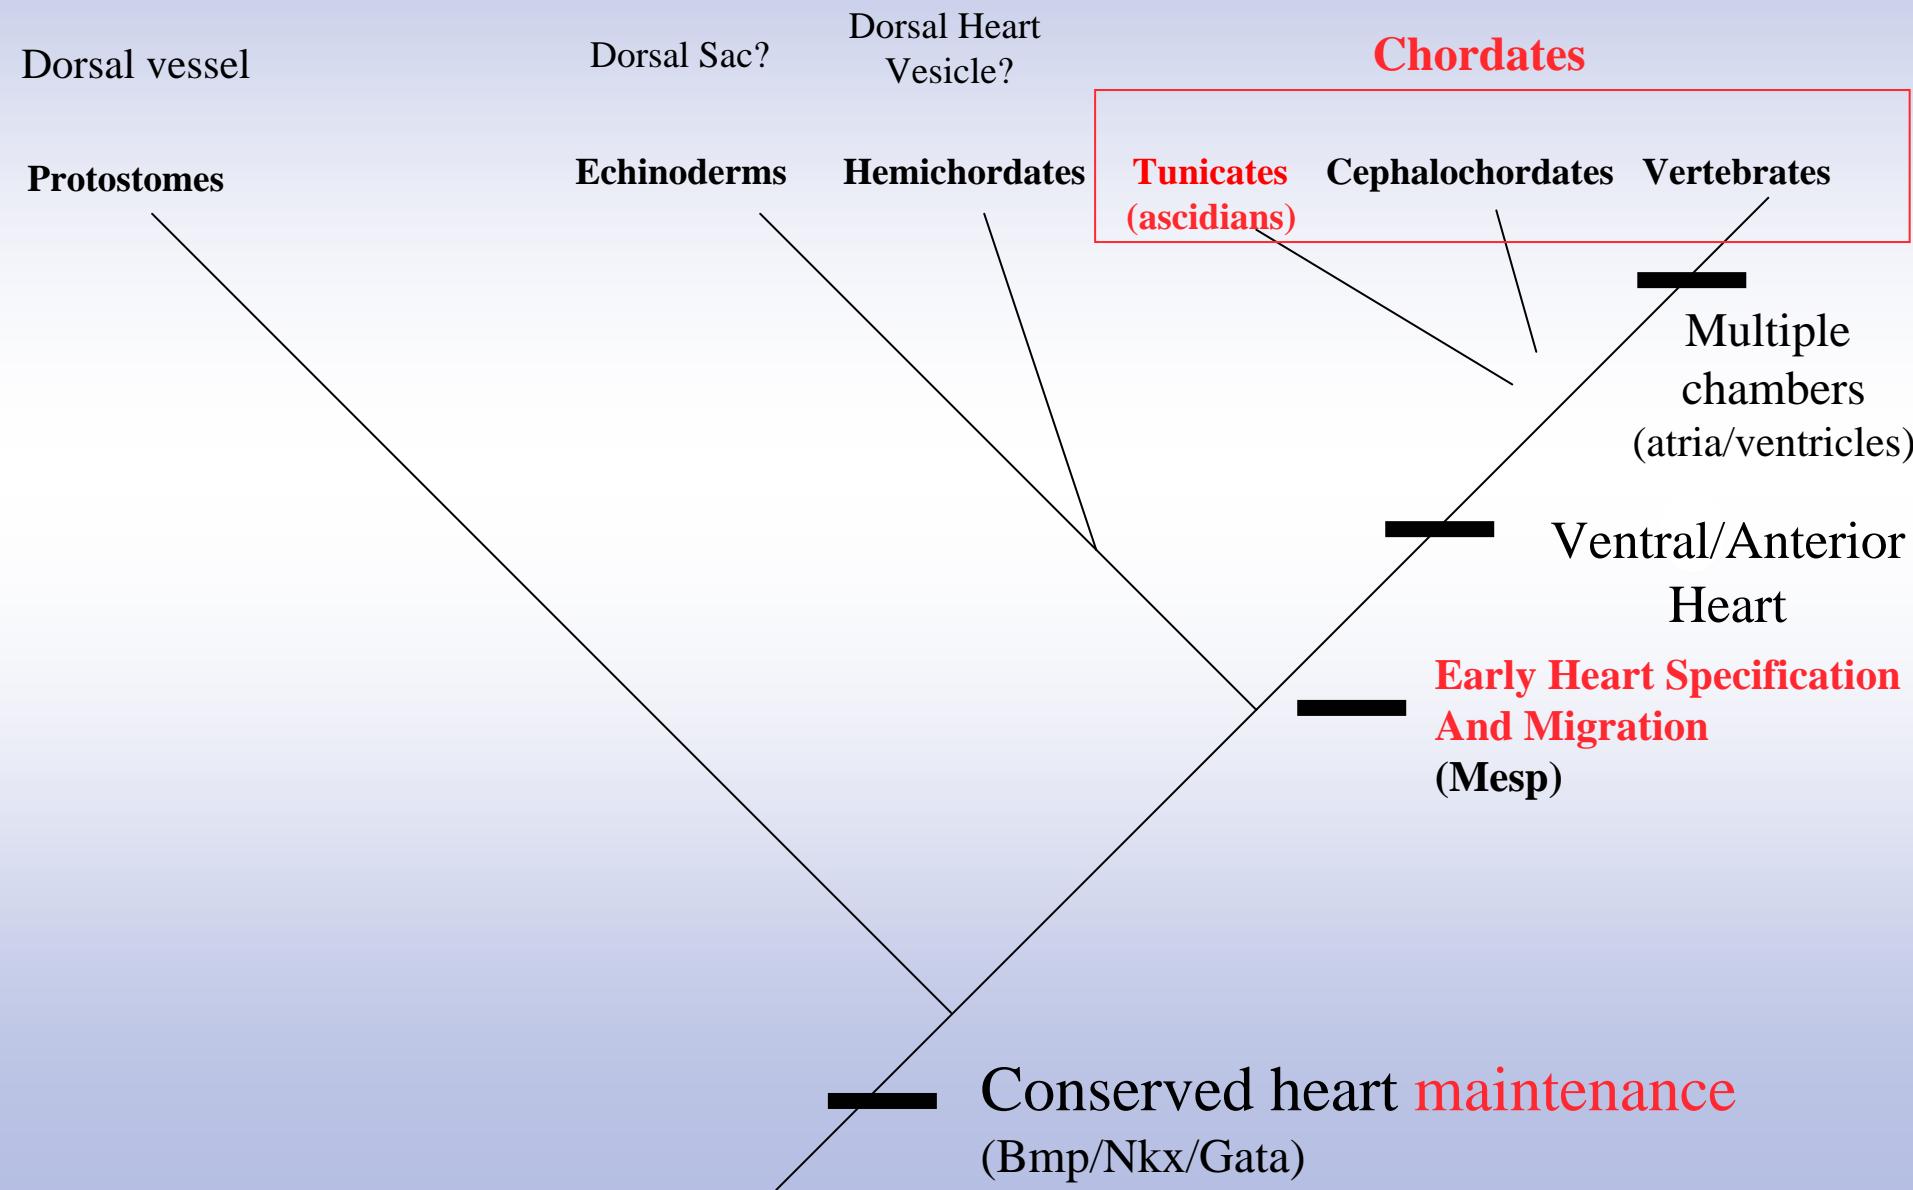

Ant. Paraxial (Cardiac) + Post. Paraxial (blood/somite)

## 2. Endoderm signal (Bmp, et al.) maintain heart fate, Wnt permits re-specification.

# Heart Evolution

# Recruitment of Mesp during chordate heart evolution?

**Known:** Only Mesp ortholog in flies (Sage) is expressed in salivary glands.

**Assumption:** Role for Mesp in heart/segmentation clock is specific to chordates.

{Test by expression assays in hemichordates, echinoderms, annelids and arthropods.}

## Hypotheses:

A. Evolution towards a muscular post-anal tail for chordate locomotion drove...

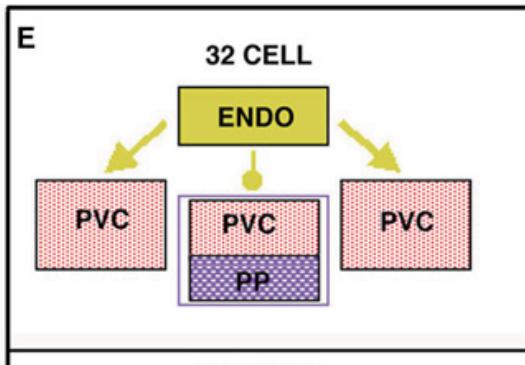

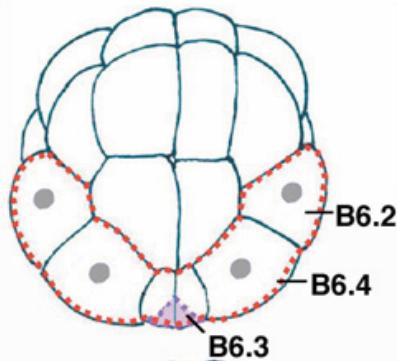

- Recruitment of Mesp to delay mesoderm differentiation, permitting dense clusters of muscle precursors to form = somites.

B. Lack of posterior heart lineage drove need for delayed heart differentiation.

C. Lack of Mesp in segmentation clock/heart is specific to Drosophila.

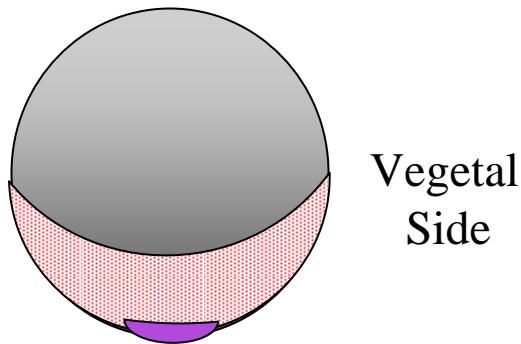

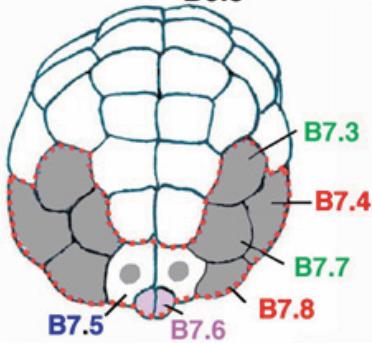

# Mesp and the Germ Plasm

A

Germ line Silencing  
(Tomioka et al; 2002)(Nishida)

B

**Mouse Mesp (Mesoderm Posterior) first isolated in subtractive screen for expression in primordial germ cells (Saga et al. 96)**

# **1. Evolutionary implications**

**a. Early vertebrate heart specification**

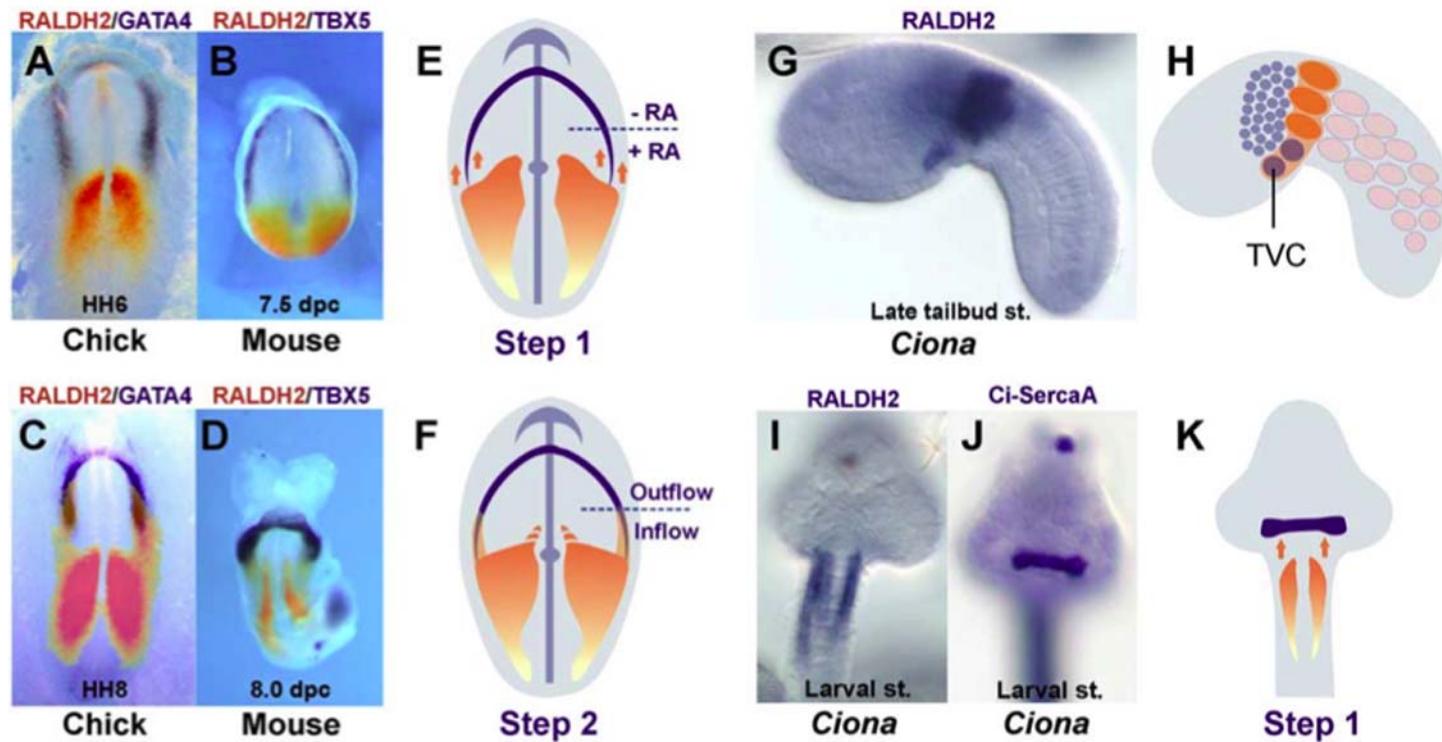

**b. Recruitment of Mesp in chordate heart dev.**

**c. Mesp and the Germ Plasm**

**d. Chamber evolution**

1. In vertebrates and Ciona, Raldh expression domain is initially caudal to heart field.

M.S. Simões-Costa et al. / Developmental Biology 277 (2005) 1–15

2. In vertebrates Raldh expression domain later spreads rostrally to help specify the atrial (inflow) chamber.

1. Raldh has conserved role in setting posterior/caudal limit of Heart
2. Raldh domain in *Ciona* (anterior tail muscle) is the precursor to the inflow (atrial) field in vertebrates.
3. Raldh domain in *Ciona* is remnant of atrial field.
4. Caudal-Rostral wave of Raldh in *Ciona*....
  - a. patterned the endoderm and was recruited for heart
  - b. patterned ancestral chambers and was lost in *Ciona*
  - c. patterns chamber precursor domains in *Ciona* heart
